Received 21 December 2006/Accepted 20 May 2007

Mycobacterium ulcerans is a slow-growing environmental bacterium that causes a severe skin disease known as Buruli ulcer. PCR has become a reliable and rapid method for the diagnosis of M. ulcerans infection in humans and has been used for the detection of M. ulcerans in the environment. This paper describes the development of a TaqMan assay targeting IS2404 multiplexed with an internal positive control to monitor inhibition with a detection limit of less than 1 genome equivalent of DNA. The assay improves the turnaround time for diagnosis and replaces conventional gel-based PCR as the routine method for laboratory confirmation of M. ulcerans infection in Victoria, Australia. Following analysis of 415 clinical specimens, the new test demonstrated 100% sensitivity and specificity compared with culture. Another multiplex TaqMan assay targeting IS2606 and the ketoreductase-B domain of the M. ulcerans mycolactone polyketide synthase genes was designed to augment the specificity of the IS2404 PCR for the analysis of a variety of environmental samples. Assaying for these three targets enabled the detection of M. ulcerans DNA in soil, sediment, and mosquito extracts collected from an area of endemicity for Buruli ulcer in Victoria with a high degree of confidence. Final confirmation was obtained by the detection and sequencing of variable-number tandem repeat (VNTR) locus 9, which matched the VNTR locus 9 sequence obtained from the clinical isolates in this region. This suite of new methods is enabling rapid progress in the understanding of the ecology of this important human pathogen.

Buruli ulcer (BU) is a skin disease caused by infection with Mycobacterium ulcerans, a slow-growing environmental mycobacterium (11). The disease has been reported in over 30 countries worldwide (9), predominantly in riverine areas with tropical and subtropical climates but also in temperate climates, such as southern Australia (10, 30). Infection with M. ulcerans can lead to extensive destruction of skin and soft tissue with the formation of large ulcers. The characteristic necrosis and ulceration is induced by an unusual diffusible cytotoxic macracyclic polyketide called mycolactone, which is produced by M. ulcerans. Mycolactone is the product of three large multienzyme complexes called polyketide synthases that are encoded by the genes mlsA1 (51 kb), mlsA2 (7 kb), and mlsB (42 kb). These genes are located on the M. ulcerans virulence plasmid known as pMUM001 (25, 29).

Although not generally a fatal condition, BU lesions can become extensive and heal by scarring. When diagnosis and treatment are delayed, sufferers are frequently left with long-term physical and cosmetic disabilities. In areas of endemicity, the combination of a suspicious skin lesion and a smear positive for acid-fast bacilli is highly suggestive of BU and can be definitively diagnosed by culture. However, due to the very slow growth of the organism, culture confirmation may take 8 to 12 weeks and treatment needs to be initiated much sooner than this to ensure an optimal outcome for the patient. The use of PCR for diagnosis of BU has been a major step forward, particularly in Australia where we have access to molecular diagnostics and where BU is increasingly common. The most commonly used target sequence for PCR is IS2404, a multicopy insertion sequence that encodes a 328-amino-acid transposase (26). Provided that diagnostic PCR is performed in a laboratory with high standards to avoid false positives, it is a reliable and rapid method for laboratory confirmation of disease caused by M. ulcerans (15).

Despite strong epidemiological evidence linking the source of M. ulcerans to swamps and slow-flowing water (16), the precise mode of transmission has yet to be elucidated. Understanding the ecology of M. ulcerans has been severely hampered by the extreme difficulty of culturing the organism directly from the environment (13, 16, 22, 24). This difficulty may be due partly to contamination by less fastidious mycobacteria that outgrow M. ulcerans. IS2404 PCR performed on DNA extracted from environmental samples has proved a major advance since its first use in the mid-1990s (22). The bacterium has now been detected in water and detritus (22, 24), aquatic insects (17) and plants (13), snails (12), and small fish (5). However, while IS2404 PCR is highly specific and sensitive for testing diagnostic specimens from humans, its application to the analysis of environmental samples is less straightforward due to PCR inhibitors and the existence of other environmen-

tal mycobacteria that may carry IS2404 (14, 18-20, 32). Approaches for increasing confidence in the interpretation of PCR-positive tests for environmental samples and for overcoming the issues surrounding primer specificity are the use of an internal probe, such as in the TaqMan assay, to confirm the identity of a PCR product and to use two or more DNA targets.

In the Australian state of Victoria, there has been a significant recent increase in the incidence of BU (also known locally as Bairnsdale ulcer) (8). With increasing numbers of clinical specimens, we sought to develop a real-time PCR method based on IS2404 to improve the turnaround time for diagnosis of *M. ulcerans* infection. We also wanted to develop additional real-time PCR assays targeting different regions in the *M. ulcerans* genome that could be used as confirmatory assays for the analysis of environmental samples. This paper describes the development of two multiplex real-time PCR assays targeting three distinct repeated sequences in the *M. ulcerans* genome: IS2404, IS2606 (20), and a sequence encoding the ketoreductase B domain (KR), present in 15 copies within the mycolactone polyketide synthase genes *mlsA1*, *mlsA2*, and *mlsB* (25). These assays have facilitated the rapid diagnosis of *M. ulcerans* disease in clinical specimens and the analysis of environmental samples in less time and with greater confidence than conventional PCR.

MATERIALS AND METHODS

**Mycobacterial strains.** Mycobacterial isolates used in this study are listed in Table 1 (also see Table S1 in the supplemental material).

**Clinical specimens.** A total of 415 primary clinical specimens received at the Victorian Mycobacterium Reference Laboratory from July 2003 to June 2005 were included in the study. These specimens consisted of 244 swabs (dry or in bacterial transport medium), 159 fresh tissue biopsies, 11 formalin-fixed, paraffin-embedded tissue sections, and 1 bone sample. Swab and fresh tissue specimens were split for DNA extraction and culture following maceration and/or homogenization in a bottle containing glass beads and phosphate-buffered saline. Specimens were cultured in BACTEC 12B bottles and on Brown and Buckle medium (11) and incubated at 31°C for up to 12 weeks.

**Environmental samples.** Mosquitoes and soil samples were collected from various locations in an area of Victoria where there is currently an outbreak of *M. ulcerans* infection. Mosquitoes were trapped using overnight mosquito traps baited with carbon dioxide and light and stored at −70°C. Both wet and dry surface soil samples from drains and soak pits were collected in sterile containers and stored for no more than 5 days at 4°C until DNA extraction was performed.

**DNA preparation.** Extraction of DNA from mycobacterial cultures was performed as previously described (6). DNA was extracted directly from swabs and homogenized fresh tissue biopsies by using the Roche AMPLICOR respiratory specimen preparation kit (Roche Diagnostics Co., Indianapolis, IN), followed by

b Numbering based on the first copy of the amplicon in pMUM001 (GenBank accession no. BX649209).
c Determined by BLAST analysis of the amplicon sequence in WASABIL, an in-house, web-interfaced MySQL database for genome analysis.
d A total of 171 were identical copies, with an additional 30 copies identified with 1-nucleotide substitutions within the primer sites which would be unlikely to prevent amplification.

RESULTS

Development of real-time PCR assays targeting IS2404, IS2606, and KR. Three TaqMan real-time PCR assays were designed using the Primer Express software package (Applied Biosystems) to detect different regions in the M. ulcerans genome, the insertion sequences IS2404 and IS2606 and the KR domain of the mls genes. These targets were chosen because they were reported to be present in multiple copies in the M. ulcerans genome and are absent in the closely related species Mycobacterium marinum (7, 26). Primers and probes were selected from the IS2404, IS2606, and KR sequences present on the M. ulcerans virulence plasmid pMUM001 (GenBank accession no. BX649209). There are two distinct sequence types among the KR domains on the plasmid, KR-A (3 copies) and KR-B (15 copies). The primers and probe for the KR real-time assay were selected from the KR-B sequence. Table 2 presents the nucleotide positions of the primers and probes designed, the corresponding amplicon sizes, the putative function of the
target, and the number of copies of each amplicon on the plasmid and chromosome. Studies of pMUM001 copy number have shown that it is present in one to two copies per cell (28). Thus, the theoretical copy numbers for the IS2404, IS2606, and KR-B target sequences in the genome of \textit{M. ulcerans} strain \textit{Agy99} are 205 to 209, 90 to 98, and 15 to 30 copies per cell, respectively (Table 2).

\textbf{Sensitivity testing of the IS2404, IS2606, and KR real-time PCR assays.} The sensitivities of the IS2404/IPC and the IS2606/KR multiplex assays were tested by performing real-time PCR on dilutions of purified \textit{M. ulcerans} genomic DNA from strain \textit{Agy99} (Table 1). During validation, the IS2606 and KR assays were evaluated with and without multiplexing. The results indicated that multiplexing the two assays did not reduce the sensitivity (data not shown). The standard curves obtained with 10-fold serially diluted genomic DNA preparations were linear over six orders of magnitude for the IS2404 assay and over five orders of magnitude for both the IS2606 and the KR assays (Fig. 1). Based on the complete DNA sequence, the predicted mass of a single copy of the \textit{M. ulcerans} genome is 5.8 fg (27). Given the actual number of copies of the target in the \textit{M. ulcerans} genome (Table 2), the IS2404 assay reliably detected 0.01 genomes, equivalent to two copies per cell, with a reliable detection limit of 0.1 genomes (equivalent to 9 copies of IS2606 and 1.5 to 3 copies of KR-B). It was noted that the \(\Delta C_T\) between the IS2606 and IS2404 assays \([\Delta C_T \text{ (IS2606-IS2404)}]\) ranged from 2.77 (for \(10^4\) genomes) to 4.1 (for 0.1 genomes), which was slightly higher than expected based on the 2.3-fold difference in target copy numbers (Table 2). The \(\Delta C_T\) between the KR and IS2404 assays increased from 1.3 (for \(10^5\) genomes) to 4.3 (for 0.1 genomes) but was generally lower than that for the \(\Delta C_T\) (IS2606-IS2404), further indicating that the IS2606 assay is less sensitive than the KR assay.

To compare the sensitivity of the IS2404 real-time PCR with the conventional gel-based PCR targeting IS2404 (31), 10-fold dilutions of purified \textit{M. ulcerans} genomic DNA were tested using both methods. The results indicated that the IS2404 TaqMan real-time PCR is 100 to 1,000 times more sensitive than the conventional single-round gel-based PCR (data not shown).

\textbf{Specificity testing of IS2404, IS2606, and KR real-time PCR assays.} To test the specificity of the assays, we conducted BLASTN searches using the IS2404, IS2606, and KR TaqMan amplicon sequences (Table 2) and performed the IS2404/IPC and IS2606/KR multiplex real-time PCRs on purified genomic DNA from (i) a diverse collection of \textit{M. ulcerans} isolates, (ii) five other recently described mycolactone-producing mycobacteria (MPM), and (iii) 24 non-MPM (Table 1), including the isolate (ITM 00-1026) previously considered to be a “missing link” between \textit{M. ulcerans} and \textit{M. marinum} because it was PCR positive for IS2404 (3). Three isolates of \textit{Mycobacterium lenti- flavum} were included, as it had previously been reported that IS2606 had been detected in a strain of this species (26).

BLASTN searches performed using the target sequences failed to identify significant homology with any other sequences in the NCBI databases. PCR amplification of all three targets was achieved for \textit{M. ulcerans} isolates from all geographic regions tested, demonstrating that the assays are able to detect \textit{M. ulcerans} strains from different parts of the world where \textit{M. ulcerans} disease occurs (Table 1). All three targets were also detected in the other MPM tested, with the exception of the strain designated \textit{M. marinum} CC240299, for which IS2606 was not detected (Table 1). None of the three targets were detected in any of the 24 non-MPM, including \textit{M. lentiflavum} (Table 1), demonstrating the specificity of the assays for MPM. It was noteworthy that the “missing link” strain, \textit{M. marinum} ITM 00-1026 (3), was not detected by the real-time assay targeting IS2404, despite the fact that a PCR product was...
amplified using the IS2404-specific primers MU1-new and MU2 (31). A BLASTN search of the GenBank database using the sequence amplified from strain ITM 00-1026 (GenBank accession no. EF14897) containing the 59-bp target region revealed only 86% identity with the equivalent region of IS2404 (GenBank accession no. BX649209), with eight nucleotide differences in the 59-bp region targeted in the TaqMan assay.

The \( \Delta C_T \) value for the detection of IS2404 and IS2606 distinguishes between \textit{M. ulcers} subsp. \textit{ulcers} and other MPM. The term \textit{M. ulcers} subsp. \textit{ulcers} has been proposed to describe the \textit{M. ulcers} genotypes which cause disease outbreaks in humans, are phylogenetically clustered on the basis of multilocus sequence types (MLST), and have high copy numbers of IS2606. These MLST types have been isolated from Africa (ST17), Southeast Asia and northern Australia (ST18), and southeastern Australia (ST20) (32). Other members of the MPM were shown to have fewer (or no) copies of IS2606 per genome. To determine whether the \( \Delta C_T \) (IS2404-IS2404) could distinguish between isolates with multiple and few copies of IS2606, regardless of the DNA extraction procedure, DNA extracts from isolates, clinical specimens, and environmental samples spiked with \textit{M. ulcers} isolate 63/04 were appropriately diluted to give C\textsubscript{2404} values of 20 to 25 and assayed for IS2606. \( \Delta C_T \) (IS2606-IS2404) values were then determined (see Table S1 in the supplemental material).

For the \textit{M. ulcers} subsp. \textit{ulcers} isolates and the DNA preparations from Victorian patient specimens and spiked environmental samples, the median \( \Delta C_T \) value was 2.37 (95% confidence interval, 2.17 to 2.79), indicating a similar ratio of IS2404 to IS2606 copy number, which has been estimated to be 2.3:1 for the sequenced strain Agy99 (27). However, \textit{M. ulcers} strains from China (ST19) and Suriname (ST16), Queensland isolate 20213/91, and the other MPM (ST9, -10, -11, -12, and -14) had consistently higher \( \Delta C_T \) values (median, 7.60; 95% confidence interval, 6.94 to 8.07), indicating fewer copies of IS2606 relative to IS2404. This difference in \( \Delta C_T \) values between the subcluster of \textit{M. ulcers} isolates with MLST types ST17, ST18, and ST20 and isolates with the other MLST types was statistically significant (\( P < 0.001 \)) and represents a valuable means of distinguishing between those \textit{M. ulcers} strains causing disease in endotherms (including humans) and other closely related mycobacteria that also harbor IS2404 and IS2606.

Application of the IS2404 TaqMan real-time assay for the detection of \textit{M. ulcers} DNA in clinical specimens. The IS2404 TaqMan assay replaced gel-based PCR as the principal method for laboratory diagnosis of suspected cases of \textit{M. ulcers} infection in Victoria in 2003. To evaluate the sensitivity and specificity of the test in a clinical context, we compared real-time PCR results with culture results for primary specimens tested over a 2-year period from July 2003 to June 2005. During that period, we tested a total of 415 primary specimens consisting of 244 swabs (dry or in transport medium), 159 fresh tissue biopsies, 11 paraffin-embedded, fixed-tissue sections and 1 bone specimen. Of these specimens, 410 were from humans (\textit{Homo sapiens}), 4 were from ringtail possums (\textit{Pseudocheirus peregrinus}), and 1 specimen was from a koala (\textit{Phascolarctos cinereus}). Forty-three specimens (10.4%) were PCR positive (22 fresh tissue biopsies, 18 swabs, and 3 paraffin sections). The \( C_T \) values ranged from 16.01 to 35.52 and averaged 25.83. Of the 40 PCR-positive specimens that were suitable for culture (excluding paraffin-embedded, fixed-tissue sections), 35 were culture positive, indicating that real-time PCR was 12.5% more sensitive than culture. All specimens that were PCR negative were culture negative. More recently, we have been able to detect \textit{M. ulcers} DNA in fine-needle aspirates from preulcerative lesions by using the IS2404 real-time PCR assay.

Application of the IS2404, IS2606, and KR real-time assays to the analysis of environmental samples. To determine the ability of the assays to detect \textit{M. ulcers} DNA in environmental samples, we first performed the IS2404/IPC and IS2606/KR multiplex PCR assays on DNA extracts from mosquito and soil samples that had been spiked with known numbers of \textit{M. ulcers}. This served to test both the inhibitory effects of mosquitoes/soil on the real-time PCR assays and the efficiency of the DNA extraction method (FastDNA kit). The results showed that all three targets were detected in DNA extracted from the sample spiked with approximately 10 organisms, with mean \( C_T \) values of 35.6 for IS2404, 37.0 for IS2606, and 36.8 for KR (Fig. 2). A single organism per sample with a \( C_T \) value of 38 to 40 was detected intermittently by using the IS2404 assay; however, the sensitivities of IS2606 and KR assays were insufficient to detect less than 10 organisms. No inhibition was observed (based on the \( C_T \) values obtained for the IPC [data not shown]). Similar results were obtained with spiked soil samples extracted using the FastDNA SPIN kit for soil, except that for certain soil samples, PCR inhibitors were present in the DNA extracts, necessitating dilution of the extracts up to 10-fold prior to inclusion in the assay.

To test whether the assays could be used to detect \textit{M. ulcers} in association with mosquitoes caught in an area where cases of infection were occurring, DNA was extracted from 42 pools of insects trapped in six different locations on the same night. Prior to extraction, mosquitoes were sorted according to species and sex. Pools contained between 1 and 23 mosquitoes. Results indicated that two DNA extracts, from pools of 22 and 23 female \textit{Aedes camptorhynchus} mosquitoes caught in the same trap, were positive for IS2404, with \( C_T \) values of 32.4 and 33.0, respectively. These extracts also tested positive for IS2606 and KR, with \( \Delta C_T \) (IS2606-IS2404) values of 2.7 and 2.8, respectively, suggesting that \textit{M. ulcers} DNA was being detected and not DNA from other MPM that we have shown to have higher \( \Delta C_T \) values (see Table S1 in the supplemental material). All extracts for which IS2404 was not detected were also negative for IS2606 and KR. DNA extracts from soil and an associated earthworm (class \textit{Oligochaeta}) collected from a nearby drain were also positive for all three targets, with \( \Delta C_T \) (IS2606-IS2404) values of 3.3 and 2.5, respectively, again suggesting that \textit{M. ulcers} DNA was present.

Further evidence that environmental samples contain the outbreak strain of \textit{M. ulcers}. To gain further evidence that the strain being detected in environmental samples by our real-time assays is the Victorian \textit{M. ulcers} outbreak strain, we developed a nested PCR targeting MUVNTR locus 9. The nested PCR was at least 10-fold more sensitive than the conventional single-round PCR. This locus was chosen, as the size and nucleotide sequence of the amplicon are specific for \textit{M. ulcers} isolates from Victoria and Africa and were different from those of other Australian strains and other MPM. The
amplification of a PCR product of the expected size was achieved for the DNA extracts from a mosquito pool, soil from a soak pit, and the earthworm. Sequencing of the PCR products confirmed that they were identical to the sequence determined for locus 9 from Victorian *M. ulcerans* strains which contain repeats A_9 and C_9 (1).

**DISCUSSION**

The number of cases of *M. ulcerans* disease in Australia continues to rise, with 66 new human cases reported in 2006 compared with 41 in 2005 and 26 in 2004 (4). With increasing numbers of clinical specimens for diagnosis as well as the need to determine the mode of transmission and the natural reservoir of the organism, rapid, sensitive, and specific molecular tests are needed. We have developed two multiplex, TaqMan, real-time PCR assays targeting three independent regions in the *M. ulcerans* genome for the detection of *M. ulcerans* DNA in clinical and environmental samples.

A TaqMan assay targeting IS_{2404} has been described previously (21); however, the sequence used for the design of this assay (GenBank accession no. AF003002) has been shown subsequently to differ from the IS_{2404} sequence derived from pMUM001 (GenBank accession no. BX649209) and the complete *M. ulcerans* genome (27). It is now known that primer F1 described by Rondini et al. (21) has a single-nucleotide mismatch, and the probe sequence (P1) has a deletion relative to the true sequence of IS_{2404}. Consequently, the assay described in the present study is more sensitive (with a detection limit of 0.01 genome copies compared with 0.2 genome copies) and robust, particularly when applied to DNA extracts derived from clinical and environmental samples, which may contain potential PCR inhibitors. The sensitivity of the assay targeting the KR-B domain was consistent with the expected number of copies of this target, although the IS_{2606} assay was slightly less sensitive, with a detection limit of 9 copies rather than 1.5 to 3 copies. Reasons for this were not explored as the assay was robust over a range of sample types and always provided consistent results.

The application of the IS_{2404} real-time PCR to 415 clinical samples demonstrated that it is a rapid, reliable, sensitive, and specific assay for the diagnosis of *M. ulcerans* infection using a wide range of clinical specimens, including swabs, biopsies (fresh as well as formalin-fixed, paraffin-sectioned tissue), and fine-needle aspirates. Comparison with culture revealed only five discrepant results. For these five PCR-positive, culture-negative specimens, all lesions were clinically consistent with *M. ulcerans* infection and the patients had epidemiological links with known regions of endemicity. Possible reasons for the failure of culture could include (i) small numbers of organisms in the specimen (the C_T values ranged from 23.2 to 33.3, equivalent to approximately 500 and 0.5 genomes per well, respectively), (ii) delay in receiving the specimen for processing, or (iii) prior antibiotic treatment. As well as being 100 to 1,000 times more sensitive than the conventional gel-based IS_{2404} PCR, the simpler closed-tube format, which avoids post-PCR handling of samples containing high numbers of amplicons, may make it easier to perform and provide quality assurance in more remote locations than gel-based PCR.

In addition to its important role in the diagnosis of *M. ulcerans* infection in humans and other animals, the IS_{2404} real-time PCR has a broad range of applications, including the analysis of environmental samples. Since environmental samples often contain complex mixtures of DNA that may generate false positives, we developed the multiplex TaqMan assay targeting IS_{2606} and the KR-B domain to complement the specificity of the IS_{2404} PCR. The ability to quantify the amount of *M. ulcerans* DNA in the sample using real-time PCR enabled the detection of differences in the relative numbers of copies of IS_{2404}, IS_{2606}, and KR in any given sample. The ΔC_T values between the IS_{2404} and IS_{2606} assays allowed for the distinction between *M. ulcerans* subsp. ulcerans isolates

![FIG. 2. Standard curve generated using a logarithmic scale by the analysis of DNA extracted from pools of 15 *Aedes camptorhynchus* mosquitoes spiked with known numbers of *M. ulcerans* organisms with the IS_{2404}, IS_{2606}, and KR TaqMan real-time PCR assays. Each 10-fold dilution was performed in quadruplicate, and the means of these replicates were used as data points. One standard deviation on either side of the mean is shown.](image)
with MLST types ST17, ST18, and ST20 and other closely related mycobacteria within the M. ulcerans/M. marinum complex that also harbor IS2404 and IS2606. The results obtained in this study regarding IS2606 copy numbers are consistent with the recent findings of Yip et al. (32).

Using these assays, M. ulcerans DNA was detected in mosquitoes and soil, without the need to use sequence capture, which has been relied on previously (24). The presence of all three targets with the expected ΔC_T (IS2606-IS2404), together with the demonstration that the size and sequence of VNTR locus 9 were the same as that amplified from the local outbreak strain, confirms that M. ulcerans DNA consistent with that of the same strain was present in these samples. However, the presence of viable bacteria has yet to be confirmed by culture.

The ability to reliably detect M. ulcerans DNA in mosquito samples was an important first step in our study investigating the hypothesis that mosquitoes play a role in the transmission of M. ulcerans infection, which is the subject of another report (P. D. R. Johnson et al., submitted for publication).

The development of this real-time IS2404 PCR assay for the diagnosis of BU has improved laboratory efficiency and reduced the risk of contamination compared with gel-based methods. Furthermore, the development of a suite of assays produced the macrolide toxin of Mycobacterium ulcerans in axenic culture and harbor these bacteria in the environment. Appl. Environ. Microbiol. 70:1097–1103.
